

Title of the project

Umweltpsychologie (Environmental Psychology)

Project period

2001 – 2010

Institution

Center for Environmental Systems Research

Project co-ordination

Prof. Dr. Andreas Ernst

Project team

Dipl. Psych. Silke Kuhn, Dipl. Psych. Roman Seidl, NN, NN

Contact

Brief description:**Keywords**

Water use, agent-based social simulation, scenarios, integrative research, decision support system

Targets

The environmental psychology part of the project has implemented a multi-agent model that simulates all households in terms of their water use decisions. A coming task is to develop and test psychological-social indicators of satisfaction and risk perception as well as orientation values of water related social sustainability.

Data

Own empirical studies yielded a substantial data basis regarding habitual water use, risk perception, attitudes toward nature and adoption of water saving innovations.

Modeling

The process-oriented multi-agent model *DeepHousehold* contains five types of agents (here: *actors*) based on 5 lifestyles (Sinus-Milieus®), and simulates the water use as well as the water related satisfaction of private households based on 10 water-usages. Each actor type (milieu) has its own preferences, i.e. the actors perceive the variables upon which they base their decisions as varying in importance: It may be very important to one actor to behave in an environmentally friendly way, whereas another actor might base his decision mostly upon financial aspects.

Based on different scenarios including diverse climatic and social constraints, a dynamic emerges which fits actual social processes. Another feature is the explicit spatial resolution of the model:

The actor types in the model are distributed according to their real distribution. This is done by using data from Microm® who use themselves the Sinus-Milieus®.

The diffusion of water saving innovations is already implemented in *DeepHousehold*. Presently, a theoretical concept of risk perception regarding climate change and drinking water is being developed and implemented. The acceptance and reactance of interventions and their possible behavioral effectiveness regarding habit formation is to be captured similarly.

These advancements of the model enable to run socio-scientific scenarios under conditions of global climate change, in order to estimate potential conflicts and risks for acceptance.

Processing

It is intended to upgrade the *DeepHousehold* model with respect to the following factors:

- Further development of psychological-social indicators for satisfaction and risk perception. These indicators are then to be used for decision support.
- Building scenarios to analyze the psychological-social indicators.
- Further validation and quality management of the model and its interactions with DANUBIA
- Integrative work to suit the realization of the decision support to the stakeholders.
- Provision of the scientific expertise of the project
